## NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS

RESEARCH MEMORANDUMTHEORETICAL ROCKET PERFORMANCE OF JP-4 FUEL WITH MIXTURES  
OF LIQUID OZONE AND FLUORINE

By Vearl N. Huff and Sanford Gordon

## SUMMARY

Theoretical rocket performance was calculated for JP-4 fuel with mixtures of ozone and fluorine. The data were estimated by means of a heat-correction equation using data for JP-4 fuel with mixtures of oxygen and fluorine. The estimated values were checked with several direct calculations. The estimated data were based upon equilibrium composition during expansion, while the directly computed data were obtained for both equilibrium and frozen composition during expansion.

The maximum value of specific impulse was 334.9 pound-seconds per pound for a combustion-chamber pressure of 600 pounds per square inch absolute and an exit pressure of 1 atmosphere.

## INTRODUCTION

Liquid-fluorine - liquid-ozone mixtures might serve as high-energy oxidants for rocket propellants. A mixture of liquid fluorine and liquid oxygen has been shown to give better performance with hydrocarbons than either 100 percent fluorine or oxygen (ref. 1). This is due to the preferential burning of fluorine with hydrogen and oxygen with carbon.

The substitution of liquid ozone for liquid oxygen provides the advantages of greater energy and density. Available information indicates that liquid-fluorine - liquid-ozone mixtures may be stable. If stable mixtures can be produced, this oxidant might have practical application. The performance of fluorine-ozone mixtures on the assumption of chemical equilibrium during expansion may be obtained from the performance of fluorine-oxygen mixtures for chemical equilibrium by applying a simple correction for the increased heat of reaction. A formula for such a correction is given in reference 2. The present report gives the specific impulse of fluorine-ozone mixtures with JP-4 fuel obtained with this correction equation and compares it with several direct computations.

## CALCULATION OF PERFORMANCE DATA

The performance data presented in this report were calculated by two methods. The first method estimates performance by means of a heat-correction equation. The second method obtains performance by direct calculation.

## Estimated Performance

Specific-impulse data for fluorine-oxygen mixtures with JP-4 fuel were corrected for the difference in heat of reaction between oxygen and ozone to obtain estimated data for fluorine-ozone mixtures with JP-4 fuel. The heat required to convert 1 gram of liquid oxygen at its boiling point to liquid ozone at its boiling point is about 726 calories per gram (ref. 3). The difference in heat per gram of propellant due to the use of ozone instead of oxygen is given by

$$\Delta h = 726 (1 - x) y \quad (1)$$

where  $x$  is the weight fraction of fuel in the propellant and  $y$  is the weight fraction of ozone in the oxidant. (Symbols are defined in the appendix.) The specific impulse corrected for this energy difference is given by

$$I^2 = I_1^2 + a \Delta h + b \Delta h^2 \quad (2)$$

where

$$a = 87.0132 \left(1 - \frac{T_e}{T_c}\right)_1$$

$$b = \frac{87.0132}{2} \left(\frac{T_e}{T_c^2}\right)_1 \left[ \frac{1}{(c_p)_c} - \frac{1}{(c_p)_e} \right]_1$$

and the subscript 1 indicates the value of the parameters before the change is made. Equation (2) is derived in reference 2 and is restricted to the assumption of chemical equilibrium during expansion. A numerical example of the use of equation (2) is given in reference 4.

The value of 726 calories per gram used in equation (1) was obtained from heat of formation and heat of vaporization data in reference 5 and specific heat data for ozone calculated from spectroscopic data of reference 6. More recent data quoted in reference 7 give a value of 711

calories per gram. This difference affects specific impulse in this report by less than 0.25 pound-second per pound.

#### Direct Computation of Performance

The estimated performance data obtained by means of equation (2) were checked by several direct calculations. The general method used to obtain directly computed data is described in reference 3.

Assumptions. - The calculations were based on the following usual assumptions: perfect gas law, adiabatic combustion at constant pressure, isentropic expansion, no friction, homogeneous mixing, and one-dimensional flow. The products of combustion were assumed to be graphite and the following ideal gases: atomic carbon C, carbon monofluoride CF, carbon difluoride  $CF_2$ , carbon trifluoride  $CF_3$ , carbon tetrafluoride  $CF_4$ , difluoroacetylene  $C_2F_2$ , methane  $CH_4$ , carbon monoxide CO, carbon dioxide  $CO_2$ , atomic fluorine F, fluorine  $F_2$ , atomic hydrogen H, hydrogen  $H_2$ , hydrogen fluoride HF, water  $H_2O$ , atomic oxygen O, oxygen  $O_2$ , and the hydroxyl radical OH. The combustion products were assumed to be expanded completely within the exit nozzle, that is, exit pressure equals ambient pressure. The graphite was assumed to be finely divided and in temperature and velocity equilibrium with the gases during the flow process.

Thermodynamic data. - The thermodynamic data for all combustion products except graphite, methane, the fluorocarbons, and water were taken from reference 3. Data for graphite were taken from reference 8, carbon monofluoride from reference 9, the remainder of the fluorocarbons from reference 10, and water from reference 11. Data for methane were determined by the rigid-rotator - harmonic-oscillator approximation using spectroscopic data from reference 6. The base used in this report for assigning absolute values to enthalpy is the same as in reference 3.

The dissociation energy of fluorine was taken to be 35.6 kilocalories per mole, and the heat of sublimation of graphite at  $298.16^\circ K$  was taken to be 171.698 kilocalories per mole (ref. 5). The heat of solution of oxygen and fluorine was taken to be zero.

Viscosity data. - The theoretical viscosities for the gases in this report were calculated by means of three types of equations or estimated. The viscosity data for  $CH_4$ , CO,  $CO_2$ ,  $F_2$ ,  $H_2$ , and  $O_2$  were calculated by the method of reference 12. The viscosities of C, F, H, HF, O, and OH were calculated by the method of reference 13, which assumes that the logarithm of viscosity is a linear function of the logarithm of temperature. The viscosity of  $H_2O$  was obtained by means of a Sutherland equation (ref. 14). The viscosities of CF,  $CF_2$ ,  $CF_3$ ,  $CF_4$ , and  $C_2F_2$  were

taken to be equal to those of CO, CO<sub>2</sub>, CH<sub>3</sub>, CH<sub>4</sub>, and C<sub>2</sub>H<sub>2</sub>, respectively. The method used to obtain the viscosities and conductivities of mixtures of combustion products is given in reference 4.

Physical and thermochemical data. - The properties of the fuel used in these calculations are typical of the JP-4 fuel delivered to this laboratory over a period of 2 years. The JP-4 fuel was assumed to have a hydrogen-to-carbon weight ratio of 0.163 (atom ratio of 1.942), a lower heat of combustion value of 18,640 Btu per pound, and a specific gravity of 0.769. Additional properties of jet fuels may be found in reference 15.

Several properties of fluorine and ozone taken from references 3, 5, 7, and 16 are listed in table I. Additional data on ozone may be found in reference 7.

Method of calculation. - The calculation procedures and the formulas used are the same as described in reference 4.

Accuracy of results. - The values presented for enthalpy, entropy, and specific impulse appear to be computed correctly to all figures tabulated. The temperature and molecular weight may in some cases be in error by a few figures in the last place tabulated. The derivatives may, in regions where they are changing rapidly, be in error by a few percent. However, because of uncertainties in thermodynamic data used, all values are probably tabulated to more places than are entirely significant.

#### THEORETICAL PERFORMANCE DATA

##### Tables

The theoretical specific impulse obtained by direct calculation and estimated by means of equation (2) is given in table II. The data used in equation (2) were obtained from results previously computed at this laboratory both published (refs. 1 and 4) and unpublished (including specific heat data for ref. 1). The estimated values of specific impulse are from 0.2 to 0.8 pound-second per pound lower than the directly calculated values for the five points for which both values were calculated. It is expected that the other estimated values given in table II are in error by about the same amount.

The maximum value of specific impulse is 334.9 pound-seconds per pound for a combustion-chamber pressure of 600 pounds per square inch absolute and an exit pressure of 1 atmosphere.

The calculated values of performance parameters and combustion products obtained by direct calculations are given in tables III to VI.

The properties of gases in the combustion chamber and the characteristic velocity are given in table III. The equilibrium values of specific heat, isentropic exponent, and characteristic velocity include the energy of dissociation. The equilibrium specific heat was calculated by means of equation (37) in reference 3. The equilibrium isentropic exponent  $\gamma = \left( \frac{\partial \ln P}{\partial \ln \rho} \right)_S$  was computed by means of equation (32) in reference 3.

The frozen values of specific heat, isentropic exponent, and characteristic velocity do not include the energy of dissociation and are computed by the conventional formulas (see ref. 17).

Tables IV and V present the values of performance parameters and combustion products at assigned temperatures and constant entropy. The values were computed directly and used to interpolate properties at the assigned pressure ratios given in table VI. A discussion of the use of derivatives such as  $n_T$ ,  $n_P$ , and  $(\partial M / \partial T)_S$  is given in reference 4. Mole fractions were computed for all 19 substances considered in this report, but those substances are omitted from table V whose mole fractions are less than  $5 \times 10^{-6}$  for all temperatures shown for a given equivalence ratio  $r$  and fluorine-to-oxygen atom ratio  $\beta$ .

Table VI presents performance data at various assigned pressure ratios from 1 to 300. Reference 4 gives an example of the use of data at the low pressure ratios to obtain pressures at the injector face.

### Figures

The specific-impulse data of table II for a pressure ratio of 20.41 are plotted in figure 1. The maximum value of specific impulse is 309.0 at an equivalence ratio of 1.508 for a fluorine-to-oxygen atom ratio of 1.942.

Figure 2 presents the maximum value of specific impulse for any percent fluorine in the oxidant. A curve of maximum specific impulse for oxygen instead of ozone is given for comparison.

The increase in maximum specific impulse due to the substitution of ozone for oxygen is summarized in the following table (combustion-chamber pressure, 600 lb/sq in. abs; exit pressure, 2 atm; pressure ratio, 20.41):

Fluorine in oxidant, percent by weight	Specific impulse, $I$ , lb-sec/lb		Increase in spe- cific impulse, lb-sec/lb
	JP-4 fuel plus fluorine-oxygen mixture	JP-4 fuel plus fluorine-ozone mixture	
0	262.3	284.3	22.0
40	281.7	295.4	13.7
70	301.0	309.0	8.0

Figures 3 and 4 present data computed by direct methods. Figure 3 shows specific impulse as a function of the logarithm of pressure ratio for frozen and equilibrium composition during expansion. The equilibrium values are from about 7 to 12 percent higher than the frozen values. The specific-impulse exponent  $n_I$  is also given.

Figure 4 presents temperature plotted against the logarithm of pressure ratio for frozen and equilibrium composition during expansion. Also shown is the temperature exponent  $n_T$ .

#### SUMMARY OF RESULTS

Rocket performance data are presented for JP-4 fuel with mixtures of ozone and fluorine. Specific-impulse data were estimated by means of a heat-correction equation from data for JP-4 fuel with mixtures of oxygen and fluorine. The estimated data were checked for several cases by direct calculations. The difference in specific impulse between the estimated and directly calculated values was from 0.2 to 0.8 pound-second per pound. This difference is negligible for many applications.

The maximum specific impulse for a combustion-chamber pressure of 600 pounds per square inch absolute is 309.0 and 334.9 pound-seconds per pound for pressure ratios of 20.41 and 40.83, respectively.

## APPENDIX - SYMBOLS

A	nozzle area, sq in.
$C_F$	coefficient of thrust; $C_F = g_c I / c^* = F / P_c A_t$
$c_p$	specific heat at constant pressure, $(\partial h / \partial T)_P$ , cal/(g)(°K)
$c^*$	characteristic velocity, $g_c P_c A_t / w$ , ft/sec
F	thrust, lb
$g_c$	gravitational conversion factor, 32.174 (lb mass/lb force) (ft/sec <sup>2</sup> )
$H_T^0$	sum of sensible enthalpy and chemical energy, cal/mole
h	sum of sensible enthalpy and chemical energy per unit mass, $\frac{\sum_i n_i (H_T^0)_i}{M(1 - n_k)}, \text{ cal/g}$
I	specific impulse, lb force-sec/lb mass
M	molecular weight, $\frac{\sum_i n_i M_i}{1 - n_k}$ , g/g-mole or lb/lb-mole
$(\frac{\partial M}{\partial T})_s$	derivative of molecular weight with respect to temperature at constant entropy, (°K) <sup>-1</sup>
n	mole fraction
$n_I$	specific-impulse exponent for fixed pressure ratio, $\left(\frac{\partial \ln I}{\partial \ln P_c}\right)_{P_c/P}$
$n_T$	temperature exponent for fixed pressure ratio, $\left(\frac{\partial \ln T}{\partial \ln P_c}\right)_{P_c/P}$
P	static pressure (sum of partial pressures), lb/sq in.
p	partial pressure, lb/sq in.

R	universal gas constant (consistent units)
r	equivalence ratio, ratio of four times the number of carbon atoms plus the number of hydrogen atoms to two times the number of oxygen atoms plus the number of fluorine atoms in propellant, $\frac{4(C) + (H)}{2(O) + (F)}$
$S_T^o$	entropy at pressure of 1 atmosphere, cal/(mole)(°K)
s	entropy per unit mass, $\frac{\sum n_i (S_T^o)_i - R \sum p_j \ln(p_j/14.696)}{M(1 - n_k)}$
T	temperature, °K
w	mass-flow rate, lb/sec
x	weight fraction of fuel in propellant
y	weight fraction of ozone in oxidant
α	oxidant-to-fuel mole ratio
β	fluorine-to-oxygen atom ratio
γ	isentropic exponent, $\left(\frac{\partial \ln P}{\partial \ln \rho}\right)_s$
ρ	density, lb/cu in.
<b>Subscripts:</b>	
c	combustion chamber
e	nozzle exit
i	product of combustion including both gaseous and solid phases
j	gaseous product of combustion
k	solid product of combustion (graphite)
P	constant pressure
$P_c/P$	constant pressure ratio

s constant entropy  
t nozzle throat  
l reference point

(Combustion-chamber pressure, 600 lb/sq in. abs.)

(a) Equilibrium composition during isentropic expansion or compression.

Temper- ature, $T$ $\text{°K}$	Temperature exponent, $\frac{\partial \ln T}{\partial \ln P_0} \frac{P_0}{T}$	Static pressure, $P$ , lb/sq in. abs	Enthalpy, $H$ , cal/g	Molecular weight, $M$	Partial derivative, $\left(\frac{\partial H}{\partial T}\right)_s$ , $(^{\circ}\text{K})^{-1}$	Isentropic exponent, $\gamma$ , $\left(\frac{\partial \ln P}{\partial \ln T}\right)_s$	Specific heat, $c_p$ , cal/(g) $(^{\circ}\text{K})$	Absor- bute vis- cosity, micro- poises	Thermal conductiv- ity, cal/(cm) (sec)(^{\circ}\text{K})	Ratio of nozzle area to throat area	Coeffi- cient of thrust, $C_T$	Specific- impulse, $I_{sp}$ , $(\frac{\partial \ln I}{\partial \ln P_0})_{T_0}$	Spe- cific im- pulse, $I$ , lb-sec/ lb
$\beta = 0$ (pure ozone); $r = 1.508$ (30.70 percent fuel)

TABLE IV. - Concluded. THEORETICAL ROCKET PERFORMANCE AT ASSIGNED TEMPERATURES FOR  
JP-4 FUEL WITH MIXTURES OF FLUORINE AND OZONE

[Combustion-chamber pressure, 600 lb/sq in. abs.]

(b) Frozen composition during isentropic expansion or compression.

Tem- per- ature, $T$ , °K	Static pressure, $P$ , lb/sq in. abs	Enthalpy, $h$ , cal/g	Specific heat, $c_p$ , cal/ $(g)^{°K}$	Isentropic exponent, $\gamma$ , $(\gamma \ln P)$ $(\gamma \ln \rho_s)$	Absolu- te vis- cosity, micro- poises	Thermal conduc- tivity, cal/(cm) (sec) $(^{\circ}K)$	Ratio of nozzle area to throat area	Coeffi- cient of thrust, $C_F$	Spec- ific im- pulse, $I$ , lb-sec lb
$\beta = 0$ (pure ozone); $r = 1.508$ (30.70 percent fuel)

<sup>a</sup>Compositions given as mole fractions; those less than  $5 \times 10^{-6}$  are shown as 0.

<sup>b</sup>Combustion-chamber conditions.

TABLE VI. - THEORETICAL ROCKET PERFORMANCE AT VARIOUS PRESSURE RATIOS FOR MIXTURES OF LIQUID

## OZONE AND FLUORINE WITH JP-4 FUEL

(Combustion-chamber pressure, 600 lb/sq in. abs.)

(a) Equilibrium composition during isentropic expansion.

Pressure ratio, $P_e/P$	Static pressure, $P_e$ , lb/sq in. abs.	Temperature, $T_e$ , °K	Temperature exponent, $n_T$ , $(\ln T_e)/(\ln c_e P_e/P)$	Enthalpy, $h$ , cal/g	Molecular weight, $M$	Partial derivative, $(\partial h)/(\partial T)_s$ , $(^{\circ}\text{K})^{-1}$	Isentropic exponent, $\gamma$ , $(\ln P_e)/(\ln T_e)$	Specific heat, $c_p$ , cal/(g °K)	Ratio of nozzle area to throat area	Coefficient of thrust, $C_f$	Specific-impulse exponent, $n_I$ , $(\ln I_e)/(\ln c_e P_e/P)$	Specific impulse, $I_e$ , lb-sec/lb
$\delta = 0.1$ (pure ozone); $r = 1.508$ (50.70 percent fuel)

TABLE VI. - Concluded. THEORETICAL ROCKET PERFORMANCE AT VARIOUS PRESSURE RATIOS FOR

## MIXTURES OF LIQUID OZONE AND FLUORINE WITH JP-4 FUEL

(Combustion-chamber pressure, 600 lb/sq in. abs.)

(b) Frozen composition during isentropic expansion.

Pressure ratio, $P_0/P$	Static pressure, $P$ , lb/sq in. abs.	Temper- ature, $T$ , °K	Enthalpy, $h$ , cal/g	Isentropic exponent, $\gamma$ , ( $\delta \ln P$ ) ( $\delta \ln \rho$ ) s	Speci- fic heat, cal/ (g)(°K)	Ratio of nozzle area to throat area	Coeffi- cient of thrust, $C_T$	Specific impulse, $I$ , lb-sec lb
$\beta = 0$ : (pure ozone); $r = 1.508$ (30.70 percent fuel)

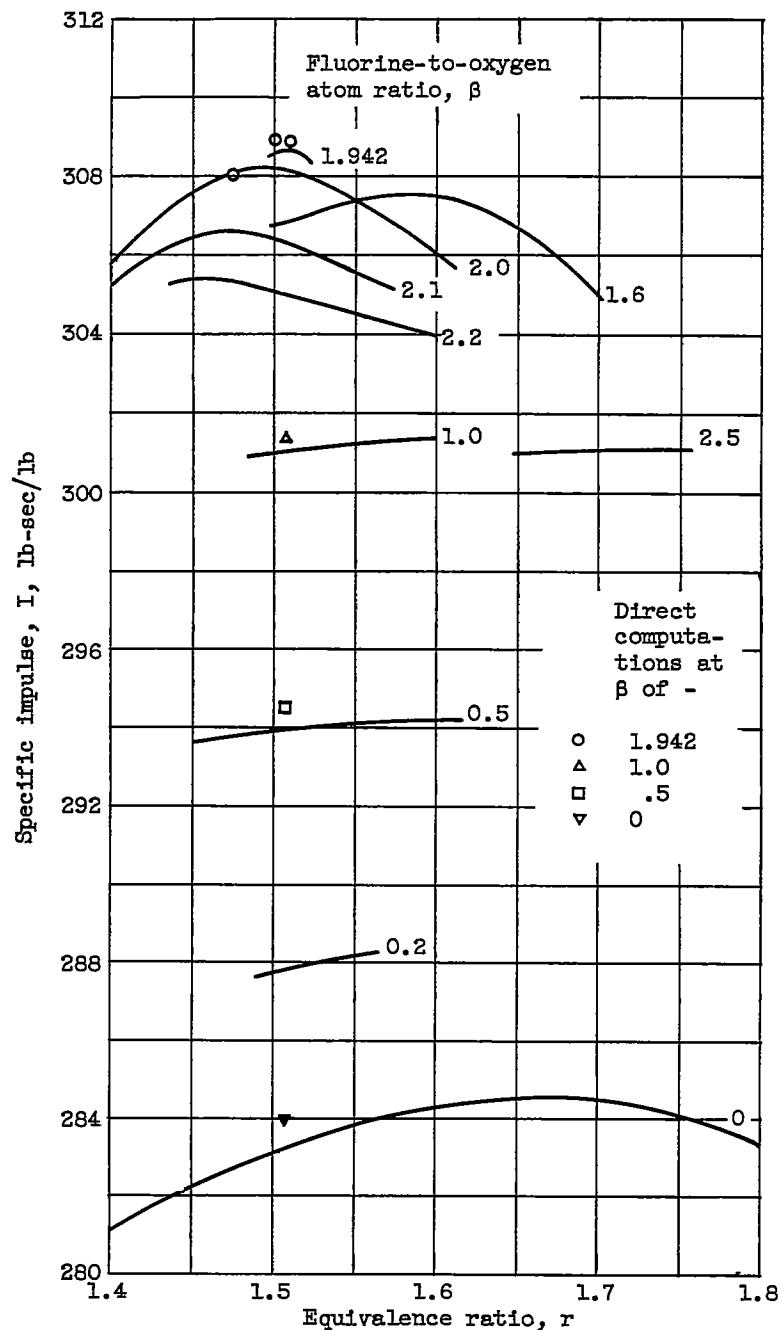

Figure 1. - Theoretical equilibrium specific impulse of JP-4 fuel with liquid-ozone - liquid-fluorine mixtures. Data calculated by means of equation (2). Combustion-chamber pressure, 600 pounds per square inch absolute; isentropic expansion to 2 atmospheres; pressure ratio, 20.41.

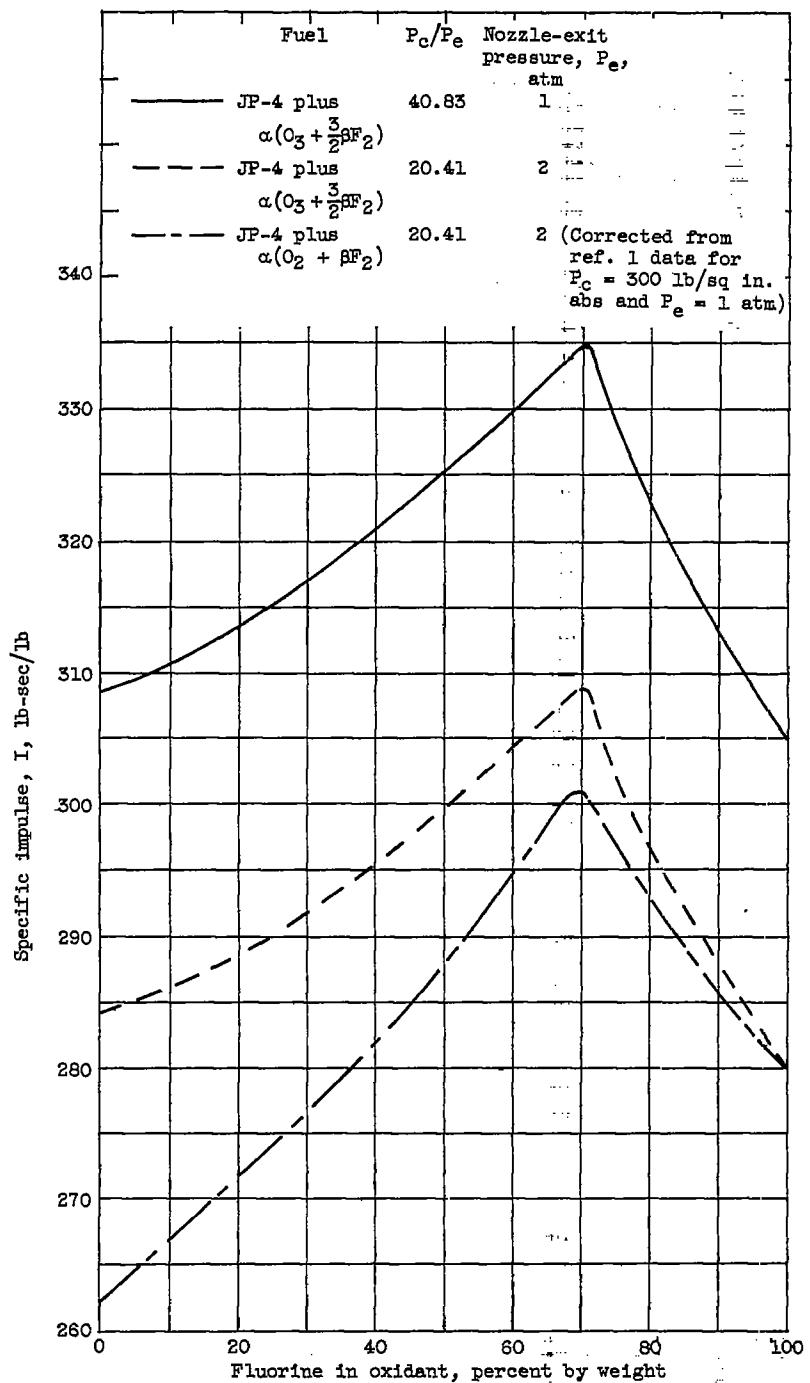

Figure 2. - Theoretical specific impulse of JP-4 fuel with liquid-ozone - liquid-fluorine mixtures and with liquid-oxygen - liquid-fluorine mixtures at equivalence ratios for which equilibrium specific impulse is maximum. Isentropic expansion from 600 pounds per square inch absolute to pressure ratio indicated assuming equilibrium composition.

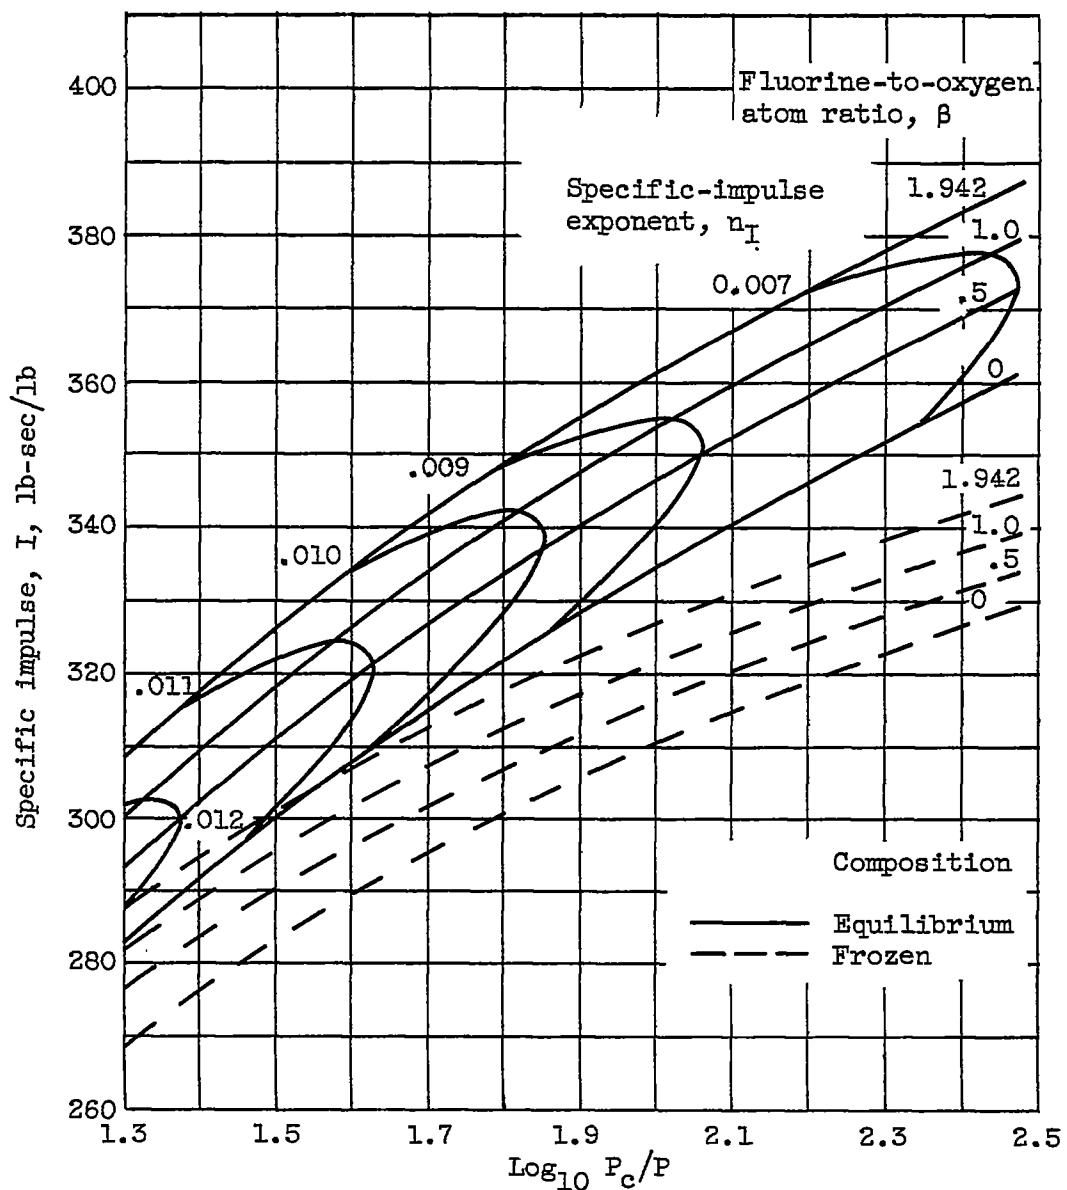

Figure 3. - Theoretical specific impulse plotted against logarithm of nozzle pressure ratio for JP-4 fuel with liquid-ozone - liquid-fluorine mixtures at equivalence ratio of 1.508. Isentropic expansion from combustion-chamber pressure of 600 pounds per square inch absolute.

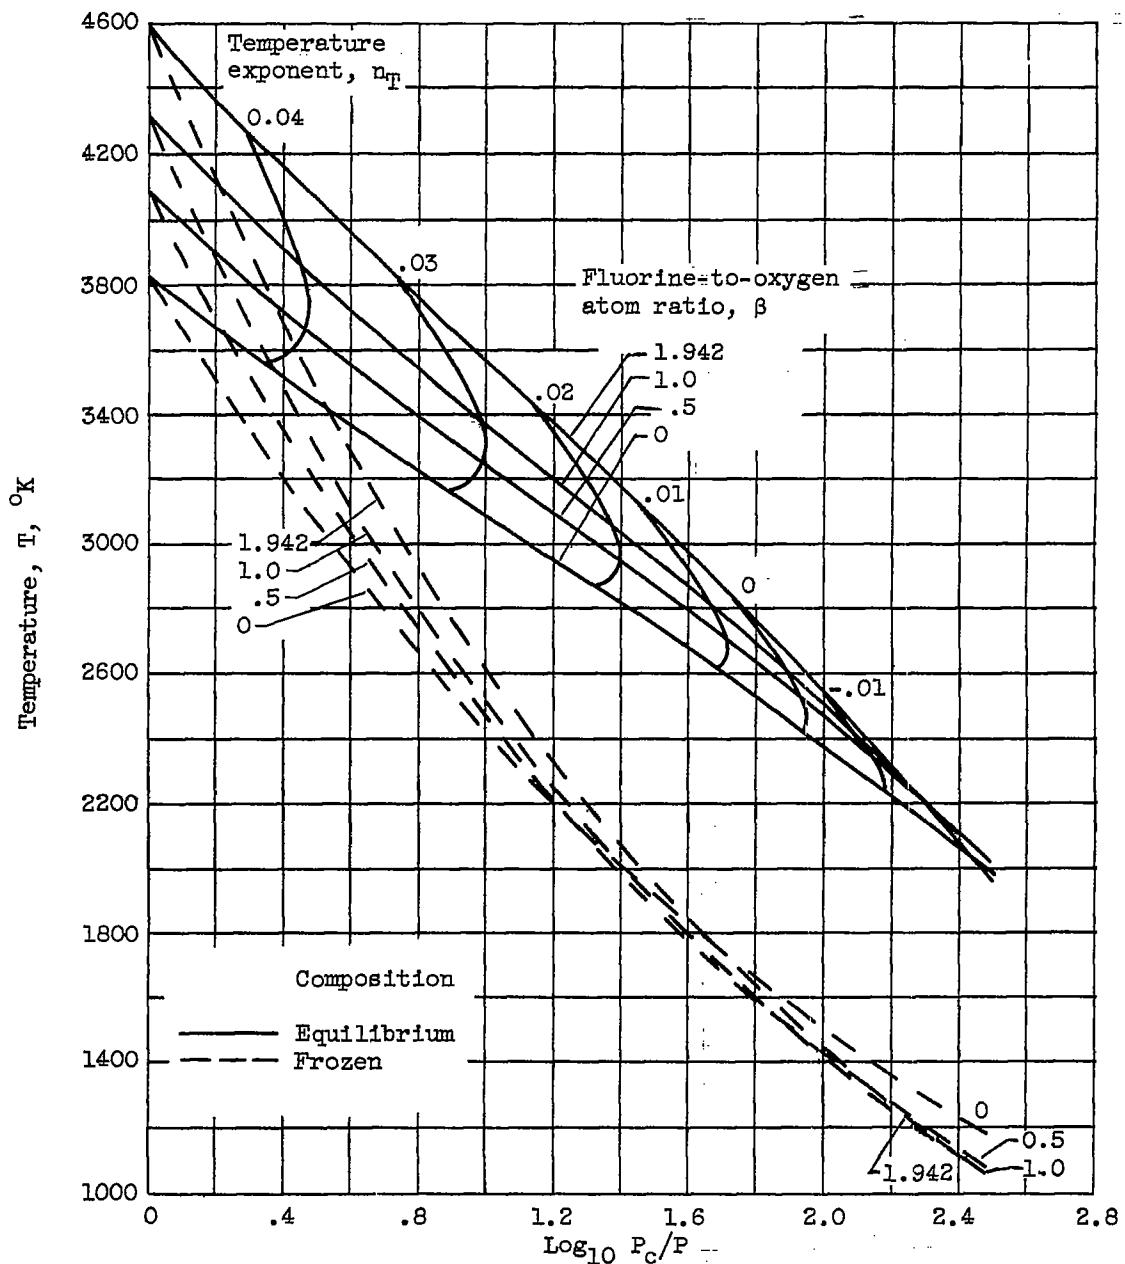

Figure 4. - Theoretical nozzle-exit temperature plotted against logarithm of nozzle pressure ratio for JP-4 fuel with liquid-ozone - liquid-fluorine mixtures at equivalence ratio of 1.508. Isentropic expansion from combustion-chamber pressure of 600 pounds per square inch absolute.
